Case Status/Priority: Completed / Regular

Case History:

hip and elbow evaluation

Case Report:

471261 KW/rb
Amelia Logan

Five digitalized radiographic images containing projections of the pelvis and elbows were submitted for evaluation. The radiographs are dated 11/7/19.

Radiographic Findings:

Both femoral heads are well seated in their respective acetabula with greater than 50% of the left femoral head and slightly greater than 50% of the right femoral head are located medial to the dorsal acetabular rims.

Both femoral heads are congruous with the acetabular rims; however, there is slight widening of the medial aspect of both coxofemoral joints.

No osteophyte formation is present on the femoral necks or acetabula.

Alignment of the patellae with the femurs is normal.

Muscle volume in both hind legs is within normal limits.

The anconeal process of both ulnae and proximocranial aspect of both radii are smooth with no evidence of osteophyte formation.

No sclerosis is associated with the ulnar notches.

Both medial coronoid processes are smooth in contour and a fragment associated with the medial coronoid processes is not identified.

Diagnosis: Normal pelvis and elbows.

Comments: Radiographic changes to suggest elbow or hip dysplasia are not present. Based on the OFA scheme of evaluating hips, the hips would be rated as good in conformation. The clinical status of the patient will determine if further assessments radiographically would be indicated to evaluate the pelvis and elbows.

Consulting Radiologist:

Kent Wallace, DVM, Ms, DACVR
